Programming in Python

GAVRILUT DRAGOS

COURSE 7

Implements function that allows one to work with time:

- Get current time
- Format time
- Sleep
- Time zone information

Details about **time** module in Python:

- Python 2: https://docs.python.org/2/library/time.html#module-time
- Python 3: https://docs.python.org/3/library/time.html#module-time

Usage:

```
Python 2.x / 3.x
import time
w = ["Mon", "Tue", "Wed", "Thu", "Fri", "Sat", "Sun"]
print ("Time in seconds:", time.time())
print ("Today :", time.ctime())
                                          Output
tmobj = time.localtime()
                                          Time in seconds: 1478936424.0649655
print ("Year :", tmobj.tm year)
                                          Today : Sat Nov 12 09:40:24 2016
print ("Month :", tmobj.tm mon)
                                          Year : 2016
                                          Month : 11
print ("Day :", tmobj.tm mday)
                                          Day : 12
print ("Day of week :", w[tmobj.tm wday])
                                          Day of week : Saturday
print ("Day from year :", tmobj.tm yday)
                                          Day from year : 317
                                          Hour
                                                      : 9
print ("Hour
            :",tmobj.tm hour)
                                          Min
                                                      : 40
print ("Min
             :", tmobj. tm min)
                                          Sec
                                                      : 24
                      :", tmobj. tm sec)
print ("Sec
```

Both **localtime** and **gmtime** have one parameter (the number of seconds from 1970). If this parameter is provided the time object will be the time computed based on that number. Otherwise the time object will be the time based on time.time () (current time) value.

```
Python 2.x / 3.x
                                           Output
                                           time.struct time(tm year=2016, tm mon=11, tm mday=12,
import time
                                                           tm hour=9, tm min=53, tm sec=47,
                                                           tm wday=5, tm yday=317, tm isdst=0)
print (time.localtime())
                                           time.struct time(tm year=2016, tm mon=11, tm mday=12,
print (time.gmtime()) —
                                                           tm hour=7, tm min=53, tm sec=47,
print (time.gmtime(100)) ——
                                                           tm wday=5, tm yday=317, tm isdst=0)
print (time.gmtime(time.time()))
                                           time.struct time(tm year=1970, tm mon=1, tm mday=1,
                                                           tm hour=0, tm min=1, tm sec=40,
                                                           tm wday=3, tm yday=1, tm isdst=0)
                                           time.struct time(tm year=2016, tm mon=11, tm mday=12,
                                                           tm hour=7, tm min=53, tm sec=47,
                                                           tm wday=5, tm yday=317, tm isdst=0)
```

Use **mktime** to convert from a time object struct to a float number. Use **asctime** member to convert from a time object to a readable representation of the time (string format).

```
Python 2.x / 3.x
import time

t = time.time()
tobj = time.localtime()
tm = time.mktime(tobj)
print (tm)
print (tm)
print (time.asctime(tobj))
Output
```

1478938309.0 1478938309.444829 Sat Nov 12 10:11:49 2016

Use **strftime** to time object to a specified string representation:

Abreviation	Description
%H	Hour in 24 hour format
%I	Hour in 12 hour format
%Y	Year (4 digits)
%m	Month (decimal)
%B	Month (name)

Abreviation	Description
%M	Minute
%S	Seconds
%A	Day of week (name)
%d	Day of month (decimal)
%p	AM or PM

Python 2.x / 3.x

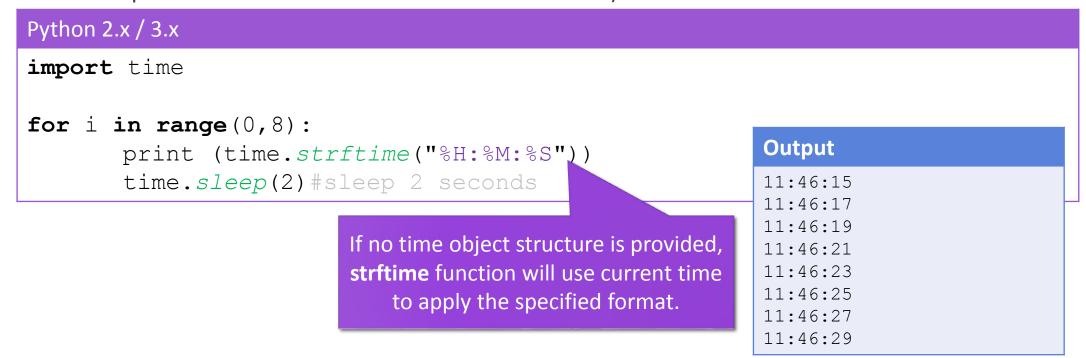

```
import time
tobj = time.localtime()
print (time.strftime("%H:%M:%S - %Y-%m-%d",tobj))
print (time.strftime("%I%p:%M:%S - %B",tobj))
print (time.strftime("%B,%A %d %Y",tobj))
```

Output

10:25:20 - 2016-11-12 10AM:25:20 - November November, Saturday 12 2016

strftime if used without a time object applies the string format to the current time.

Time module also has a function **sleep** that receives one parameter (the number of seconds the current script has to wait until it continues its execution).

Implements function that allows one to compute different cryptographic functions:

- o MD5
- o SHA-1
- o SHA-224
- SHA-384
- o SHA-512

Details about **hashlib** module in Python:

- Python 2: https://docs.python.org/2/library/hashlib.html
- Python 3: https://docs.python.org/3/library/hashlib.html

Each hashlib object has an **update** function (to update the value of the hash) and a **digest** or **hexdigest** function(s) to compute the final hash.

```
Python 2.x / 3.x
import hashlib
m = hashlib.md5()
m. update (b"Today")
m.update(b" I'm having")
m.update(b" a Python ")
m.update(b"course")
                                              Output
print (m.hexdigest())
                                              9dea650a4eab481ec0f4b5ba28e3e0b8
import hashlib
print (hashlib.md5(b"Today I'm having a Python course").hexdigest())
```

Each hashlib object has an **update** function (to update the value of the hash) and a **digest** or **hexdigest** function(s) to compute the final hash.

```
Python 2.x / 3.x
import hashlib
                                     The <b> prefix in front of a string is ignored in
m = hashlib.md5()
                                     Python 2. In Python 3 means that the string is a
m. update(b')Touay )
                                     byte list. update method requires a list of bytes
m.update(b" I'm having")
                                      (not a string). However, in Python 2 it can be
m.update(b" a Python ")
                                             used without the prefix <b>
m.update(b"course")
print (m.hexdigest())
import hashlib
print (hashlib.md5(b"Today I'm having a Python course").hexdigest())
```

Hashes are often use on files (to associate the content of a file to a specific hash).

```
Python 2.x / 3.x
import hashlib

def GetFileSHA1(filePath):
    m = hashlib.sha1()
    m.update(open(filePath, "rb").read())
    return m.hexdigest()

print (GetFileSHA1("< a file path >"))
Output

cad7a796be26149218a76661d316685d7de2d56d
```

While this example is ok, keep in mind that it loads the entire file content in memory !!!

The correct way to do this (having a support for large files is as follows):

```
Python 2.x / 3.x
import hashlib
def GetFileSHA1(filePath):
    try:
        m = hashlib.sha1()
        f = open(filePath, "rb")
        while True:
            data = f.read(4096)
             if len(data) ==0: break
            m.update(data)
        f.close()
        return m.hexdigest()
    except:
        return ""
```

Python has several implementations for data serialization.

- JSON
- Pickle
- Marshal

Documentation for JSON:

- Python 2: https://docs.python.org/2/library/json.html
- Python 3: https://docs.python.org/3/library/json.html

JSON functions:

- o **json.dump** (obj, fp, skipkeys=False, ensure_ascii=True, check_circular=True, allow_nan=True, cls=None, indent=None, separators=None, default=None, sort_keys=False, **kw)
- json.dumps(obj, skipkeys=False, ensure_ascii=True, check_circular=True, allow_nan=True, cls=None, indent=None, separators=None, default=None, sort_keys=False, **kw) → to obtain the string representation of the obj in JSON format
- json.load(fp, cls=None, object_hook=None, parse_float=None, parse_int=None, parse_constant=None, object_pairs_hook=None, **kw)
- json.loads(s, encoding=None, cls=None, object_hook=None, parse_float=None, parse_int=None, parse_constant=None, object_pairs_hook=None, **kw)

Usage (serialization):

```
Python 2.x / 3.x
                             serialization.json
import json
                             FileAddr
                                         000 001 002 003 004 005 006 007
                                                                            Text
d = \{ "a": [1, 2, 3], 
                             00000000
                                         123 034 099 034 058 032 116 114
                                                                            {"c": tr
                                         117 101 044 032 034 097 034 058
                             800000008
                                                                           ue, "a":
       "b":100,
                                         032 091 049 044 032 050 044 032
                             000000016
                                                                           [1, 2,
       "c":True
                                         051 093 044 032 034 098 034 058
                             000000024
                                                                            3], "b":
                             000000032
                                         032 049 048 048 125
                                                                            100}
s = json.dumps(d)
open("serialization.json", "wt") .write(s)
print (s)
```

Output

{"a": [1, 2, 3], "b": 100, "c": true}

Usage (de-serialization):

```
import json

data = open("serialization.json","rt").read()
d = json.loads(data)
print (d)

import json

d = json.load(open("serialization.json","rt"))
print (d)
```

Output

```
{"a": [1, 2, 3], "b": 100, "c": true}
```

Pickle is another way to serialize objects in Python. The serialization is done in a binary mode.

Pickle can also serialize:

- Functions (defined using def and not lambda)
- classes
- Functions from modules

Documentation for PICKLE:

- Python 2: https://docs.python.org/2/library/pickle.html
- Python 3: https://docs.python.org/3/library/pickle.html

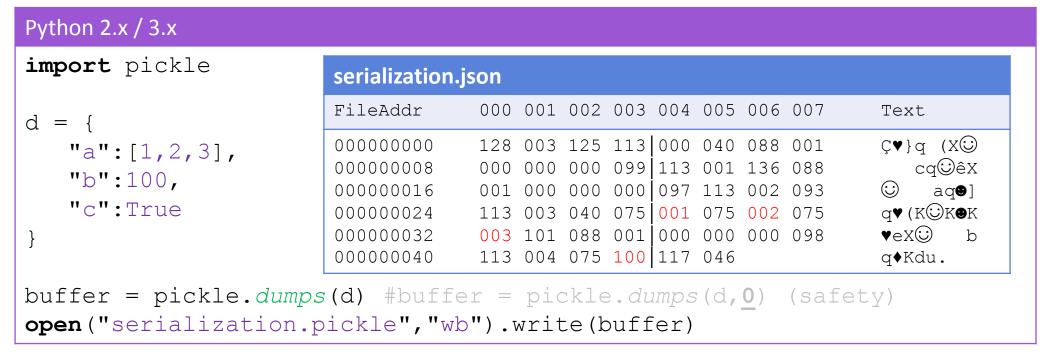

PICKLE functions:

- o pickle.dump (obj, file, protocol=None, *, fix imports=True)
- pickle.dumps(obj, protocol=None, *, fix_imports=True) → to obtain the buffer representation of the obj in pickle format
- o pickle.load(file, *, fix_imports=True, encoding="ASCII", errors="strict")
- o pickle.loads(byte_object, *, fix_imports=True, encoding="ASCII", errors="strict")

PICKLE support multiple version. Be careful when you serialize with Python 2 and try to deserialize with Python 3 (not all version supported by Python 3 are also supported by Python 2).

If you are planning to switch between versions, either check pickle.HIGHEST_PROTOCOL to see if the hightest protocol are compatible, or use **0** as the protocol value.

Usage (serialization):

Pickle need a file to be open in binary mode!

Usage (de-serialization):

```
Python 2.x / 3.x
import pickle

data = open("serialization.pickle", "rb").read()
d = pickle.loads(data)
print (d)
import pickle

d = pickle.load(open("serialization.pickle", "rb"))
print (d)
```

Output

```
{"a": [1, 2, 3], "b": 100, "c": true}
```

Marshal module

Marshal is another way to serialize objects in Python. The serialization is done in a binary mode. Designed for python compiled code (pyc). The binary result is platform-dependent !!!

Marshal functions:

- o marshal.dump (value, file, [version]) marshal
- o marshal.dumps(value, [version]) > to obtain the binary representation of the obj in marshal format
- marshal.load(file)
- marshal.loads(string/buffer)

Documentation for Marshal:

- Python 2: https://docs.python.org/2/library/marshal.html#module-marshal
- o Python 3: https://docs.python.org/3/library/marshal.html#module-marshal

Marshal module

Usage (serialization):

Python 2.x / 3.x

```
import marshal

d = {
    "a":[1,2,3],
    "b":100,
    "c":True
}
```

```
serialization.json
FileAddr
             000 001 002 003 004 005 006 007
                                                 Text
                                                 √r©cTr©a
00000000
            251 218 001 099 084 218 001 097
00000008
            091 003 000 000 000 233 001 000
                                                      \Theta
            000 000 233 002 000 000 000 233
000000016
            003 000 000 000 218 001 098 233
                                                     r⊕b⊕
000000024
             100 000 000 000 048
000000032
```

```
buffer = marshal.dumps(d)
open("serialization.marshal", "wb").write(buffer)
```

Marshal module

Usage (de-serialization):

```
Python 2.x / 3.x
import marshal

data = open("serialization.marshal", "rb").read()
d = marshal.loads(data)
print (d)
import marshal

d = marshal.load(open("serialization.marshal", "rb"))
print (d)
```

Marshal serialization has a different format in Python 2 and Python 3 (these two are not compatible).

```
Output
{"a": [1, 2, 3], "b": 100, "c": true}
```

Random module

Implements different random base functions:

- random.random() → a random float number between 0 and 1
- random.randint(min,max) → a random integer number between [min ... max]
- o random.choice(list) → selects a random element from a list
- random.shuffle(list) → shuffles the list
- random.sample(list,count) → creates another list from the current one containing count elements

Details about **random** module in Python:

- Python 2: https://docs.python.org/2/library/random.html
- Python 3: https://docs.python.org/3/library/random.html

Random module

Usage:

Python 2.x / 3.x

```
import random

print (random.random())
print (random.randint(5,10))

l = [2,3,5,7,11,13,17,19]
print (random.choice(1))
print (random.sample(1,3))

random.shuffle(1)
print (1)
```

Output

```
0.9410874890940395
9
5
[19, 17, 11]
[13, 17, 11, 5, 2, 19, 7, 3]
```

Implements different functions to work with a zip archive:

- List all elements from a zip archive
- Extract files
- Add files to archive
- Get file information
- o etc

Details about **zipfile** module in Python:

- Python 2: https://docs.python.org/2/library/zipfile.html
- Python 3: https://docs.python.org/3/library/zipfile.html

Listing the content of a zip archive:

Output

MathOps/ 0 0
MathOps/Complex/ 0 0
MathOps/Complex/Series.py 117 79
MathOps/Complex/__init__.py 38 38
MathOps/Simple/ 0 0
MathOps/Simple/Arithmetic.py 54 52
MathOps/Simple/Bits.py 60 55
MathOps/Simple/__init__.py 87 84
MathOps/__init__.py 30 30
a.py 43 43
all.csv 62330588 8176706

To extract a file from an archive:

```
Python 2.x/3.x

import zipfile
z = zipfile.ZipFile("archive.zip")
z.extract("MathOps/Simple/Arithmetic.py", "MyFolder")
z.close()
```

Arithmetic.py will be extracted to "MyFolder/MathOps/Simple/Arithmetic.py"

To extract all files:

```
Python 2.x / 3.x
import zipfile
z = zipfile.ZipFile("archive.zip")
z.extractall("MyFolder")
z.close()
```

A file can also be opened directly from an archive. This is usually required if one wants to extract the content somewhere else or if the content needs to be analyzed in memory.

```
Python 2.x/3.x
import zipfile

z = zipfile.ZipFile("archive.zip")
f = z.open("MathOps/Simple/Arithmetic.py")
data = f.read()
f.close()
open("my_ar.py", "wb").write(data)
z.close()
```

Method **open** from zipfile returns a file-like object. You can also specify a password: Format: ZipFile.open(name, mode='r', pwd=None)

The following script creates a zip archive and add files to it:

```
import zipfile

z = zipfile.ZipFile("new_archive.zip","w",zipfile.ZIP_DEFLATED)
z.writestr("test.txt","some texts ...")
z.write("serialization.json")
z.write("serialization.json", "/dir/a.json")
z.writestr("/dir/a.txt","another text ...")
z.close()
```

writestr method writes the content of a string into a zip file. write methods add a file to the archive.

When creating an archive one can specify a desire compression: ZIP_DEFLATE, ZIP_STORED, ZIP_BZIP2 or ZIP_LZMA.
